# Recap : PS Fudge Factors

## Recap of MC22 Study:

- Was unable to reproduce mc22 PS fudge factors calculated for the ALPs int note (2024)
  - Insufficient detail and code available from this study
- Found that difference between MC and data was likely to be  $< 20\%$  quoted in the analysis
- Utilised a 4 bin approach (i.e. splitting events by the total momentum of the two lowest momentum tracks) to fit the data/mc
  - [0-75], [75-150], [150-225], [225) GeV
- Full results and method found [here](#) (last meeting) and in further detail [here](#) (alprino meeting)

## Updates for MC24 Approach:

- Use 3 bins (( [0-75],[75-150],[>150] GeV) ) instead of 4
  - New samples have lower stats than MC22 sample
  - Near impossible to get a decent fit for final momentum bin i.e. last two bins combined
- Improved fitting (?)
  - Using log likelihood method instead of chi-squared (default)
  - Use integral of function in bin rather than center of bin

# Recap : PS Fudge Factors Approach

## Select Photon Conversion Events

- Three good tracks
- Opposite charge for the two lower momentum tracks
- Calo  $E/p > 0.7$

## Extract MPV of Fit

For each momentum bin  
([0-75],[75-150],[>150] GeV) :

- Plot **E Dep** for each layer of PS
- Apply **landau fit**
- Extract **MPV** of fit
- Plot **mean momentum vs MPV** of fit

## Samples

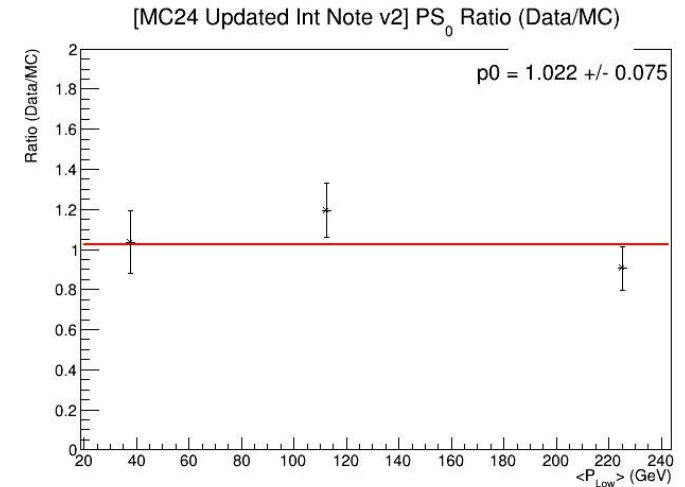

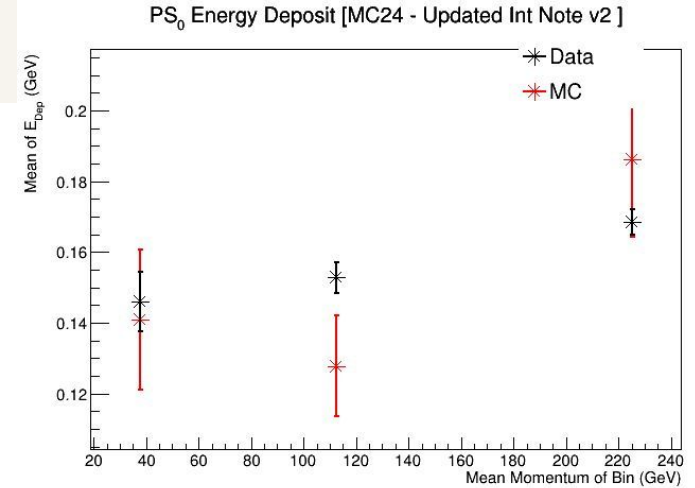

- MC24 PG Muon Samples (MC100043/44)
- 2022 & 2023 Data

## Calculate Fudge Factor

- Take **ratio (Data/MC)** for each energy distribution mean, in each momentum bin respectively
- **Fit ratios** with a horizontal fit
- **Extracted height** of fit to give fudge factor

# MC 24 PS Fudge Factors: PSo

- Small difference between data and MC
- In TI12 studies see a difference of  $\sim 2\%$ , in the test beam studies see a difference of  $\sim 5\%$

Test Beam (2024 MC)

Variable	Correction factor
Preshower Layer 0	$1.051 \pm 0.061$
Preshower Layer 1	$0.977 \pm 0.034$
Preshower Ratio	$1.036 \pm 0.032$

TI12 (2024 MC)

Variable	Correction factor
Preshower Layer 0	$1.022 \pm 0.075$
Preshower Layer 1	$0.950 \pm 0.053$
Preshower Ratio	$0.914 \pm 0.028$

# MC 24 PS Fudge Factors: PS1

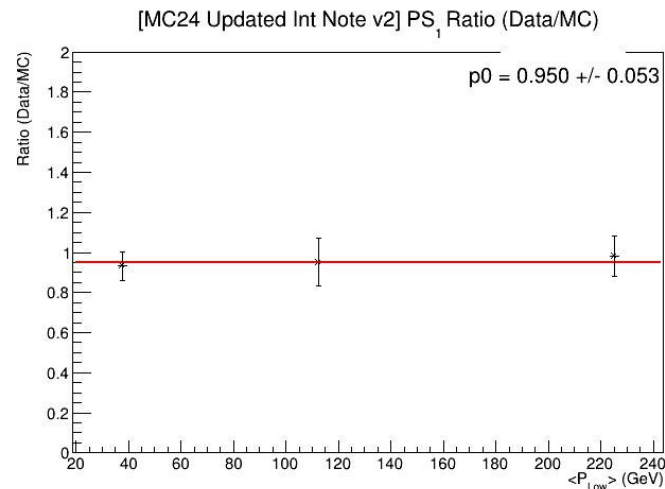

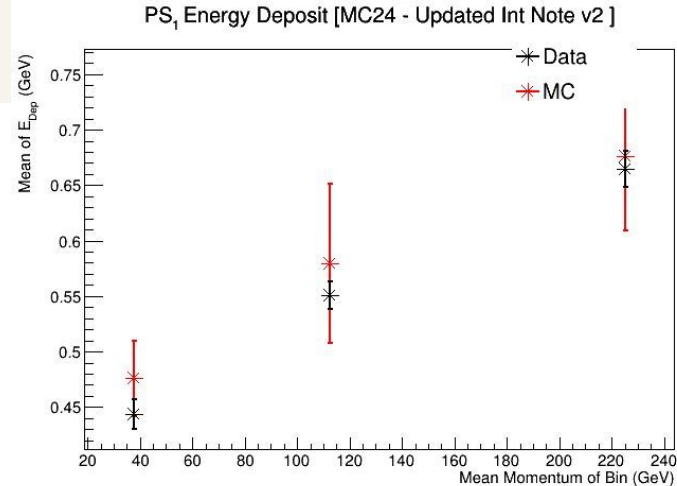

- Generally good agreement between data and mc
  - Largest uncertainty arises from mc stats
- See a slightly larger difference in ti12 studies than in TB studies (5% vs 3 %)

Test Beam (2024 MC)

Variable	Correction factor
Preshower Layer 0	$1.051 \pm 0.061$
Preshower Layer 1	$0.977 \pm 0.034$
Preshower Ratio	$1.036 \pm 0.032$

TI12 (2024 MC)

Variable	Correction factor
Preshower Layer 0	$1.022 \pm 0.075$
Preshower Layer 1	$0.950 \pm 0.053$
Preshower Ratio	$0.914 \pm 0.028$

# MC 24 PS Fudge Factors: PS Ratio

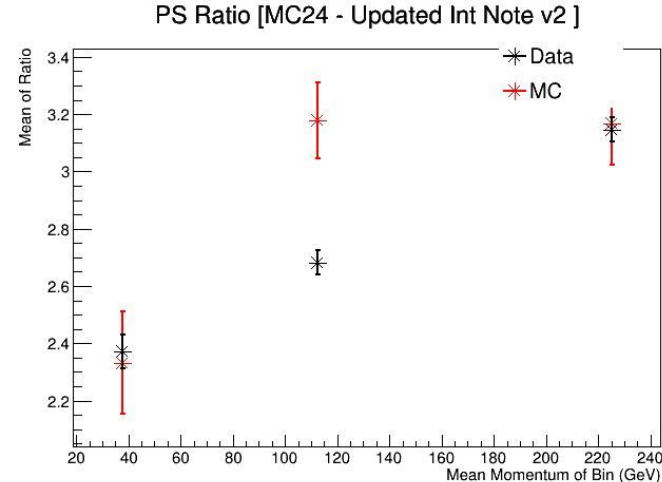

- Seems to be the largest difference between mc and data seen in the ti12 study
- Improving fit (i.e. using likelihood fit) doesn't seem to have too much of an impact
  - 0.901 vs 0.914 as data/mc ratio

Test Beam (2024 MC)

Variable	Correction factor
Preshower Layer 0	$1.051 \pm 0.061$
Preshower Layer 1	$0.977 \pm 0.034$
Preshower Ratio	$1.036 \pm 0.032$

TI12 (2024 MC)

Variable	Correction factor
Preshower Layer 0	$1.022 \pm 0.075$
Preshower Layer 1	$0.950 \pm 0.053$
Preshower Ratio	$0.914 \pm 0.028$

# Summary

- ALPtrino note now circulated and comments been addressed
  - Version 2 circulated this week (can be found [here](#))
- Concluded study on ps fudge factors using mc24 samples
  - Included in the updated note
- Analysis scripts cleaned up
  - Includes README for running each analysis
  - Will be pushed to main faser repo by the end of day
- Starting placement on monday at the Guardian
  - Full time on placement until April

## V1 (Dec 2025)

# Overview of Analysis

- The ALP analysis has observed a significant selection of neutrinos in the control region (CR).
  - CR is now our region of interest
- Uses RDF framework
  - Used in A' (2023) and ALP (2024) analyses.
- Utilises predefined neutrino regions
  - Identified in the ALPs background analysis
- Targets 2022–2024 data,
  - Totalling  $\sim 177 \text{ fb}^{-1}$ .
- Goal:
  - Detect electron neutrinos using the FASER electronic detector.
- Signal is CC Electron Neutrinos ( with NC Electron and Muon neutrinos both contributing to the background)

## Baseline Cuts

- No signal in Veto or VetoNu
- Timing Signal < 40 pC

# Overview of regions

- Utilising regions used for neutrino background in ALPs analysis
- Regions defined by PS ratio and PS1 nMIP (and utilising baseline cuts):
- **Magnet:**
  - PS1 nMIP > 10
  - PS ratio < 1.5
- **Other:**
  - PS1 nMIP > 10
  - PS ratio < 4.5 & > 1.5
- **PS:**
  - PS1 nMIP > 10
  - PS ratio > 4.5
- **Calo:**
  - PS1 nMIP < 10
